

Advanced Novel Randomization Implementation in REDCap for Clinical Trials:

Overview of REDCap Randomization and Introduction of Covariate-Adaptive Randomization Techniques

Jody D. Ciolino, PhD

Associate Professor
Department of Preventive Medicine – Biostatistics and Informatics
Northwestern University
Feinberg School of Medicine

Disclaimer / Disclosures

The views presented today are my own. They do not represent those of my institution, my funders, nor my networks at large.

Most of my funding comes from the National Institutes of Health (NIH); I serve as an external consultant for the Trial Innovation Network (TIN).

Overview

- Basic randomization in REDCap (1.0)
- Why do we randomize, and why would we adapt?
 - Issues around chance imbalances
 - Types of randomization methods that we may consider
 - What are adaptive methods?

Basic Randomization Features in REDCap (1.0)*

- *Institutions may vary*
- *Newest version of REDCap (2.0) has advanced features – will be discussed later*

Randomization in REDCap

REDCap 1.0

- Allows for custom **pre-generated** (i.e., not adaptive) randomization list
- Must be tied to a single event in a single “Arm”
- Important to consider using differing user rights:
 - Setup (programmer/analyst/statistician)
 - Dashboard (unblinded personnel)
 - Randomize (unblinded personnel performing randomization)
- To set up: select appropriate option(s) on the Project Setup checklist tab...

Project status: Development

Completed steps 6 of 9

🔁 Set up a randomization model

The randomization module will help you implement a defined randomization model within your project, allowing you to randomize your subjects (i.e. records in your project).

Go to [Set up randomization](#)

Setting up Randomization in REDCap

Stratified on sex →

“study_arm” is the randomization field →

STEP 1: Define your randomization model

This step will allow you to define the randomization model you will be implementing and all its parameters, which includes defining strata (if applicable) and optionally randomizing subjects per group/site (if a multi-site study).

A) Use stratified randomization?

It is often necessary to ensure equal treatment among a number of factors. Stratified randomization is the solution to achieve balance within one or more subgroups, such as gender, race, diabetics/non-diabetics, etc. By choosing strata (multiple choice criteria fields), you may then be able to ensure balance within those subgroups. [Tell me more](#)

Choose strata (criteria fields used for stratification; may specify up to 14 multiple choice fields)

sex (Sex as defined at birth) ▼ for Baseline (Arm 1: Main Assess ▼)
Add another stratum

B) Randomize by group/site?

If this is a multi-center/multi-site project (or something similar), you may want to stratify the randomization by each group/site. You can select an existing multiple choice field that represents the groups/sites, OR you can use Data Access Groups to stratify by group/site.

C) Choose your randomization field

This is the field where the allocated randomization (treatment) group will be saved and stored, and is where the Randomize button will appear on your data collection form.

study_arm (Randomized study arm:) ▼ for Baseline (Arm 1: Main Assess ▼)

Save randomization model Erase randomization model

STEP 3: Upload your allocation table (CSV file)

Once you have created your custom allocation table as a CSV file and made sure that you kept the format prescribed in the template files from Step 2 above, you may now upload the file below. It will be checked for any possible errors first before it is accepted and stored in REDCap. Please note that you will need to create two different allocation tables: one to be used for testing while your project is in development status and the other for use when in production status. Below are some important reminders before you begin uploading your allocation tables.

Reminders:

- Once your project is in production status, the allocation tables will become locked and unmodifiable.
- Be sure to include more assignments in your allocation table than you think you will need (to accommodate possible drop-out and drop-in of subjects).
- Record names (e.g., study ID) should NOT be included as a column in your allocation table, but only the fields listed in the example files from Step 2 above.

Upload allocation table (CSV file) for use in PRODUCTION status

Choose File No file chosen

Upload File

Randomization Notes

- Always add a “cushion”
- Always test thoroughly with study team involved
- Tables will be locked once in production
- **Development randomization table CANNOT be the same as the production table**
- Blinded studies are rather difficult to work out logistically (possible, but may need to be creative with this – restrict access and/or use code for randomization field)...

Randomization Logistics for Blinded Studies

Example Study: Maintaining the blind and ensuring drug kits correctly corresponded to the right arm required some additional thought

“Trick” - made our randomization field the “kitnumber” – no longer 0s and 1s...

[kitnumber]	Drug Kit Number	dropdown
		1492556 1492556
		1754916 1754916
		1663910 1663910
		1944231 1944231
		1525094 1525094
		1175102 1175102
		1842499 1842499
		1262338 1262338
		1270111 1270111

Randomization Logistics for Blinded Studies

Example – output .csv file from randomization script

blockID	blockSize	rnum	kitnumber	trt	sequence
1	6	0.492557	1492556	Treatment codes here (0s and 1s)	1
1	6	0.754916	1754916		2
1	6	0.66391	1663910		3
1	6	0.944232	1944231		4
1	6	0.525095	1525094		5
1	6	0.175102	1175102		6

This is what was uploaded into REDCap

Switching Gears:

Why do we randomize, and why would we adapt?

Why do we randomize?

- Randomness in treatment assignment also allows for valid statistical inferences in clinical trials (**independence** assumption)
- Primarily to **prevent bias**
 - **Selection bias**
 - **Accidental bias**

Why do we need to worry about (im)balance?

First, intuitively...we care about 'face validity'

- When we report on a trial using the typical 'Table 1', we hope to see comparable study arms with respect to key influential variables...

Characteristic	Study Arm 1 (N=114)	Study Arm 2 (N=120)	Overall (N=234)
	N(%) or Mean(std)	N(%) or Mean(std)	N(%) or Mean(std)
Age, years	56 (12)	54 (11)	55 (11)
Male sex (at birth)	63 (55)	54 (45)	117 (50)
...			
...			
History of Myocardial Infarction (MI)	80 (70)	20 (17)	100 (43)

- **Note** that random allocation ensures that baseline variables will be 'balanced', on **average**

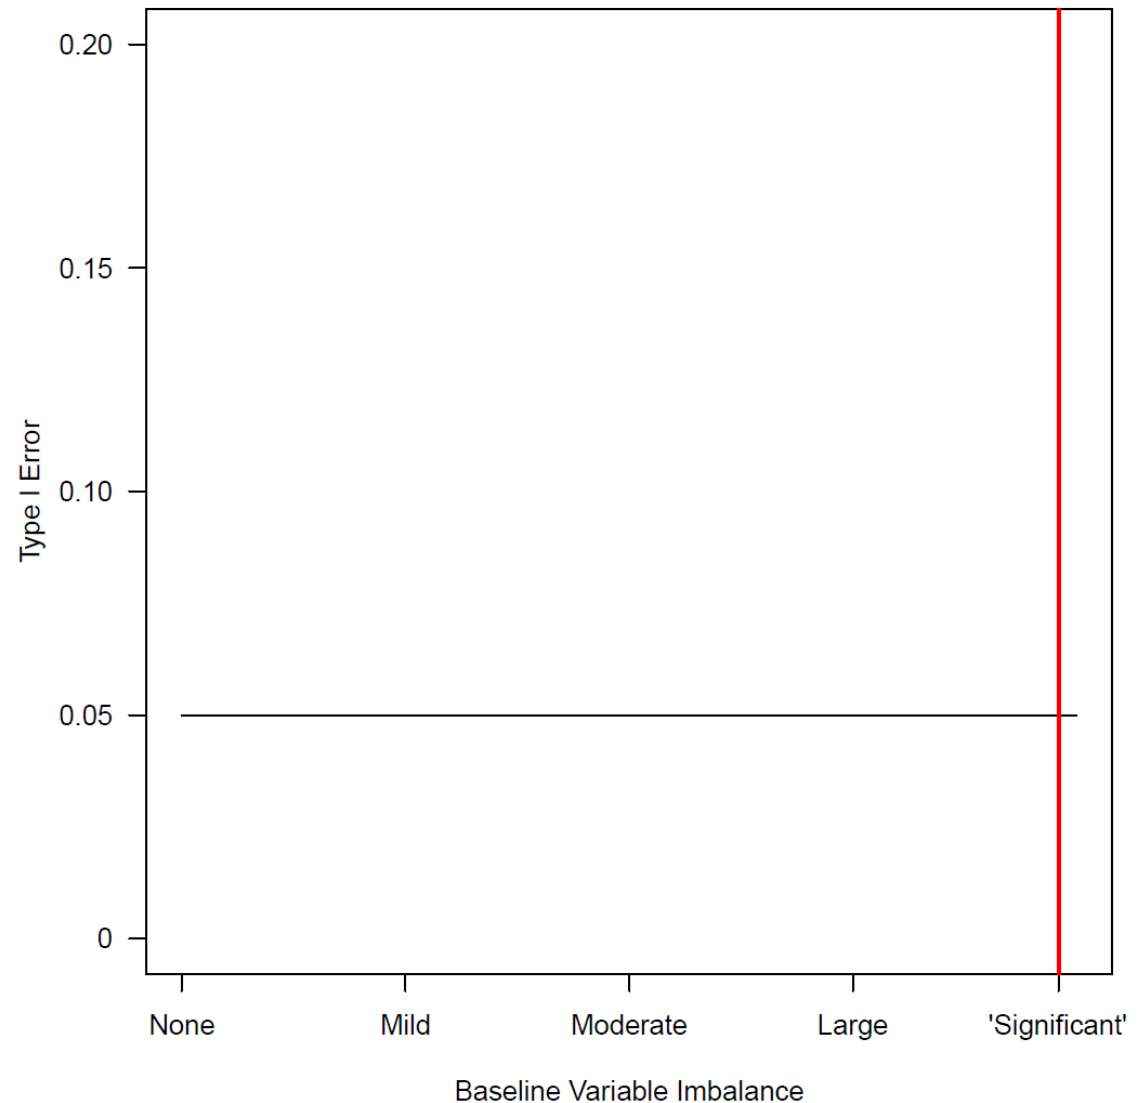

Why do we need to worry about (im)balance?

Second, statistically...there will be chance imbalances that may be nontrivial

- The **expected** level of baseline variable imbalance = 0
- BUT, a single clinical trial is just **1 realization** of **a random phenomenon**
- **Chance imbalances** are possible and **guaranteed** – every single randomized trial will exhibit some sort of imbalance across study arms
 - The (covariate) **distributions will not be identical**
 - We are not (and cannot be) matching participants across arms with respect to all variables

Consider the relationship between type I error and baseline variable imbalance...

- Assume randomized trial with 2 study arms and some continuous outcome
- X-axis: baseline variable imbalance
- Y-axis: type I error (unadjusted case)

Consider the relationship between type I error and baseline variable imbalance...

- If we have **chance imbalance** for some variable that is **not important** in predicting outcome
- → type I error will not be affected by these chance imbalances in that non-influential variable

However, if we have a somewhat influential variable at baseline, any imbalance in that variable will begin to have an affect on analyses (if we do not account for them in some way)

This visual illustrates the effect on power (y-axis) vs. baseline variable imbalance

Note: that these are examples of hypothetical scenarios and the effect depends on direction of imbalance (for instance, are we 'favoring' intervention arm or placebo arm?)

What can we do about these issues with imbalance in randomized trials?

- → it seems a good idea to give the randomization a little help in '**controlling imbalance**' in key baseline variables
- There are several options for controlling imbalance (i.e., moving away from simple random allocation)

Adaptive Randomization Algorithms

What are they? How do they work? Why not just 'stratify'?

Types of Randomization Methods

- Fixed Allocation
 - Simple (Complete)
 - Block
 - Stratified

- **Adaptive Randomization**
 - **Baseline characteristics: covariate-adaptive**
 - Response: response-adaptive

Adaptive Randomization Algorithms

What are they? How do they work? Why not just 'stratify'?

Types of Randomization Methods

- Fixed Allocation
 - Simple (Complete)
 - Block
 - **Stratified – perhaps the most common/well known**
- Adaptive Randomization
 - **Baseline characteristics**
 - Response

Digression on Stratification...

Idea: stratify (categorize important variables), then perform randomization scheme within those categories

Example

- Example: **Sex (M/F)** and **Myocardial Infarction (MI) History (yes/no)**
group = important predictors
- We have **4 strata** (2 x 2)
- Within each stratum, apply the blocked design

Stratified Block Design

Issues with Stratified Block

- Unfilled blocks may present a problem with efficiency
- Must **categorize** continuous variables
- **As number of strata** increase, performance becomes similar to simple randomization
 - **Example:** Clinical center (assume 5), sex (2 categories), age (4 categories: 21-30,30-35,36-40,>40 years), baseline disease status (mild, moderate, severe)
 - Each center has $2 \times 4 \times 3 = 24$ strata within which we need to apply a randomization scheme!
 - Thus, $5 \times 24 = 120$ strata total!
- Requires **pre-generated lists**: may be electronic, sealed envelopes, pharmacy list, etc. → opportunity for error
- There are also some statistical issues: efficiency and 'deterministic' assignments

Adaptive Randomization Algorithms

What are they? How do they work? Why not just 'stratify'?

Most methods fall under the heading of “Minimization”

- Proposed by Taves, Simon, Pocock (1970s)
- Assignment to treatment arm is determined by minimizing imbalance between study arms in terms of prognostic covariates
- Have the ability to incorporate many covariates
- **Marginally** control imbalances in key baseline variables (rather than within strata and all possible combinations of strata)

Examples of Covariate-Adaptive Methods

- Minimization (Taves, 1974; Pocock & Simon, 1975)
- Optimal Biased Coin Randomization (Atkinson, 1982)
- Optimal Biased Coin with Covariates Randomization (Atkinson, 1999)
- **Minimal Sufficient Balance (Zhao, Hill, & Palesch, 2015)**
- Common-Scale Minimal Sufficient Balance (Johns et al., 2022)

Adaptive Randomization Algorithms

What are they? How do they work? Why not just 'stratify'?

Idea...first determine how we measure “imbalance” for each variable (LOTS of options)

1. Choose imbalance function (D) to minimize for each variable (weight each variable, if desired)
2. Let overall imbalance, D = sum of imbalance for all variables
3. For **incoming participant**, calculate D under assignment to each possible treatment
 - a. Take into account that participant’s covariate information AND all previous allocations
 - b. Look at what would happen to overall imbalance if we assign to one study arm over another
4. Assign participant to arm with smallest D with higher probability: (0.5,1]

(Covariate) Adaptive Randomization Algorithms - Benefits

- Can handle a **large number** of covariates (especially when compared to stratification)
- **May not need to categorize continuous variables**, depending on algorithm
- Can ensure imbalance control with very high probability (less likely to have large chance imbalances)
- Can be **expanded** to include additional covariates over the course of the study
- Can adapt to...
 - **Randomization errors**
 - **Withdrawals prior to intervention/data collection**
 - **Correct for erroneously entered data**

(Covariate) Adaptive Randomization Algorithms - Considerations

These methods are very powerful and efficient, but they do require work and planning

- Data collection platform and randomization interface between the platform
 - e.g., If using REDCap → algorithm needs to be run outside of REDCap, and then result patched back in
- Who will be running the algorithm, on what machine, and what sort of redundancy is required?
- Data collection **timing** in relation to timing of randomization
 - **How fast** does this need to occur?
 - How likely is it that an individual is assigned an intervention/study drug ID/kit number, but then dropout prior to receipt?
- How is the **blind** maintained (if relevant)?

(Covariate) Adaptive Randomization Algorithms - Considerations

These methods are very powerful and efficient, but they do require work and planning

- These algorithms are **complicated** – it is not something that you can often ‘set and forget’
- Require **front-end** investment: **testing, testing, testing** + troubleshooting
- **Care** should be taken in choosing the method of randomization/algorithm with respect to the covariates of interest, study infrastructure, and available personnel.
 - Will we have covariates collected in a timely manner?
 - Are there specific timeframes within which randomization must occur?
 - How will algorithms be run?
 - What if something breaks?

**End of 1st Segment – Thank
you for your attention!**

Minimal Sufficient Balance

Marilyn Palettas

Center for Biostatistics

Disclosure

- No relevant disclosures

Overview

- Introduction of Minimal Sufficient Balance (MSB)
- Implementation in active clinical trial
- REDCap walk-through

Why Balanced Groups Matter

Avoiding Chance Imbalances

Even properly randomized trials can have groups differ in baseline covariates that are relevant prognostic factors

Impact on Outcomes

Imbalanced baseline covariates may skew treatment effect estimation

Loss of Power

Imbalance across important baseline prognostic factors during randomization may result in significant loss in statistical power to detect treatment differences, even if these factors are adjusted for in analysis

Limitations of Standard Methods (1 of 3)

Simple Randomization

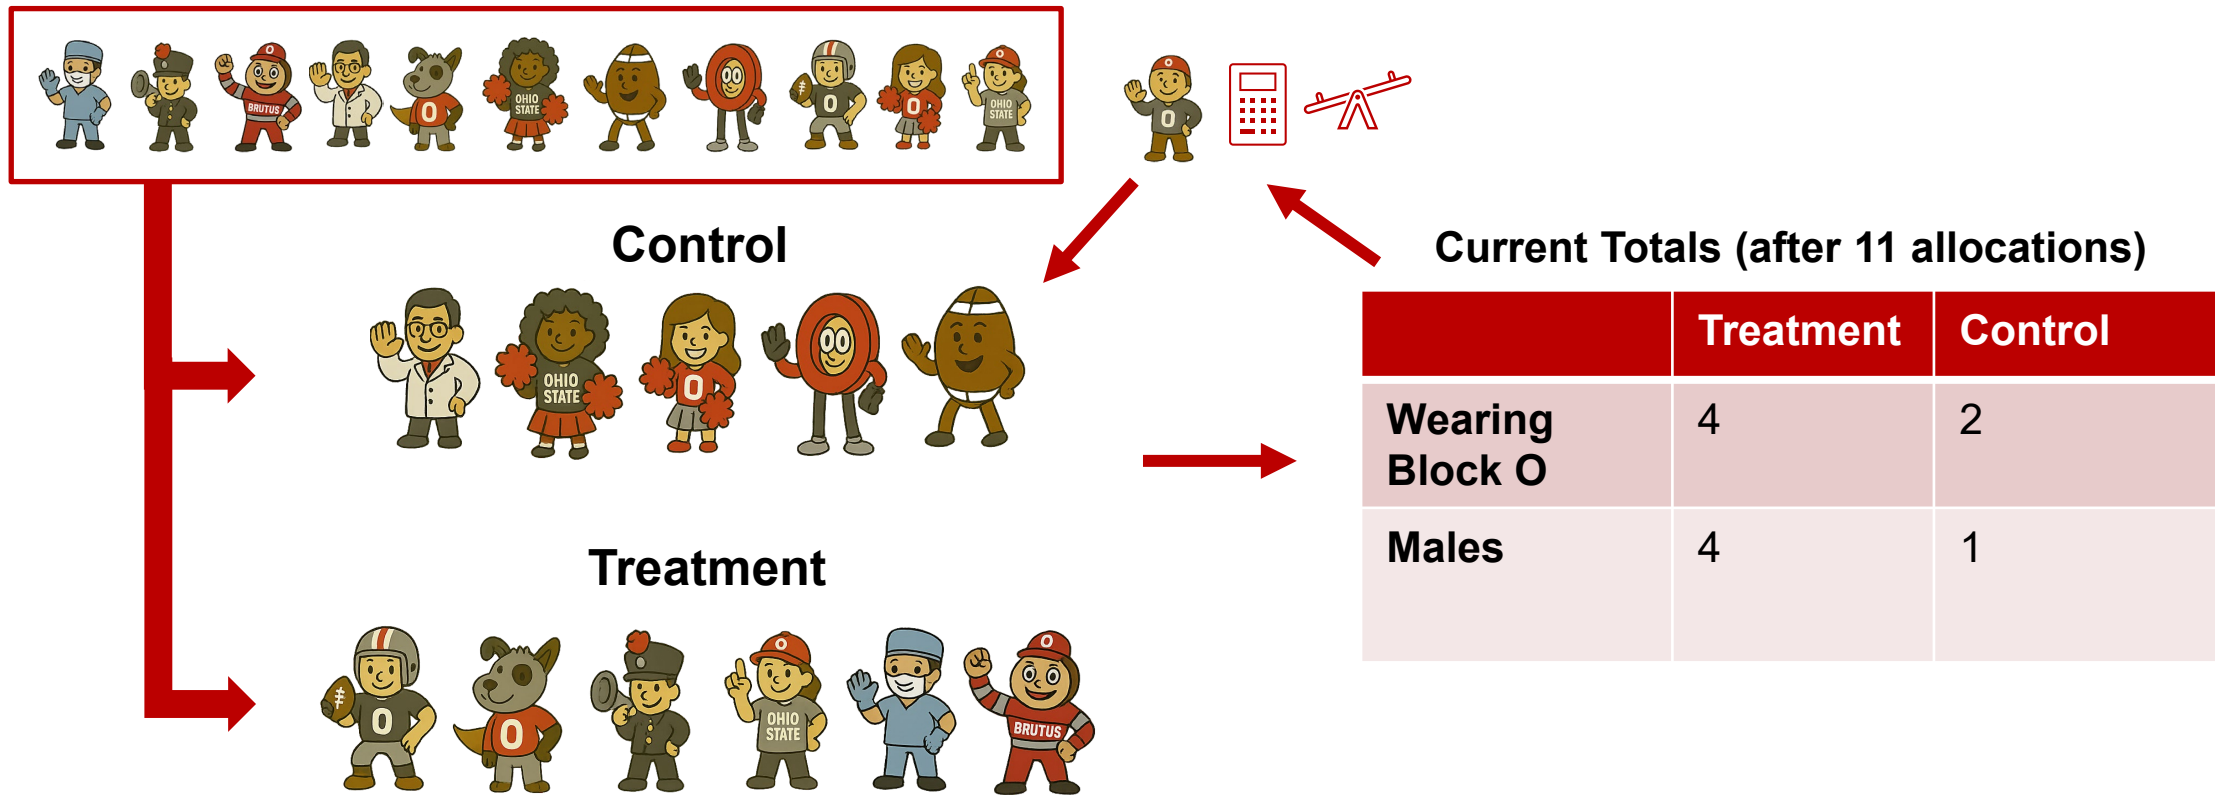

Limitations of Standard Methods (2 of 3)

Stratified Randomization

Limitations of Standard Methods (3 of 3)

Minimization

What is Minimal Sufficient Balance?

Covariate-Adaptive Design

MSB dynamically uses baseline information to decide how to allocate the next participant with minimal but sufficient constraint

Inclusive of Key Covariates

Include all important baseline factors – even continuous ones – without categorizing them

Monitoring Imbalance

Continuously monitors balance using statistical tests as a real-time measure of covariate distribution

"Minimal" Intervention

Intervenes only if imbalance exceeds a preset tolerance, using a biased coin method rather than forced assignment

Benefits of using MSB

Balanced Baseline

Effectively balances treatment groups across multiple covariates, including continuous ones

Better Interim Decisions

Ensures interim data aren't distorted by uneven baseline risk factors

Preservation of Randomness

Maintains allocation unpredictability and guards against selection bias

Reduced Bias

Prevents serious imbalances, reducing potential for baseline-driven bias in outcomes

Improved Statistical Power

Trials can more sensitively detect true treatment effects with balanced groups

How MSB Decides the Next Assignment

"Voting" by Covariates

Each covariate "votes" on where the next patient should go based on current imbalance

Counting the Votes

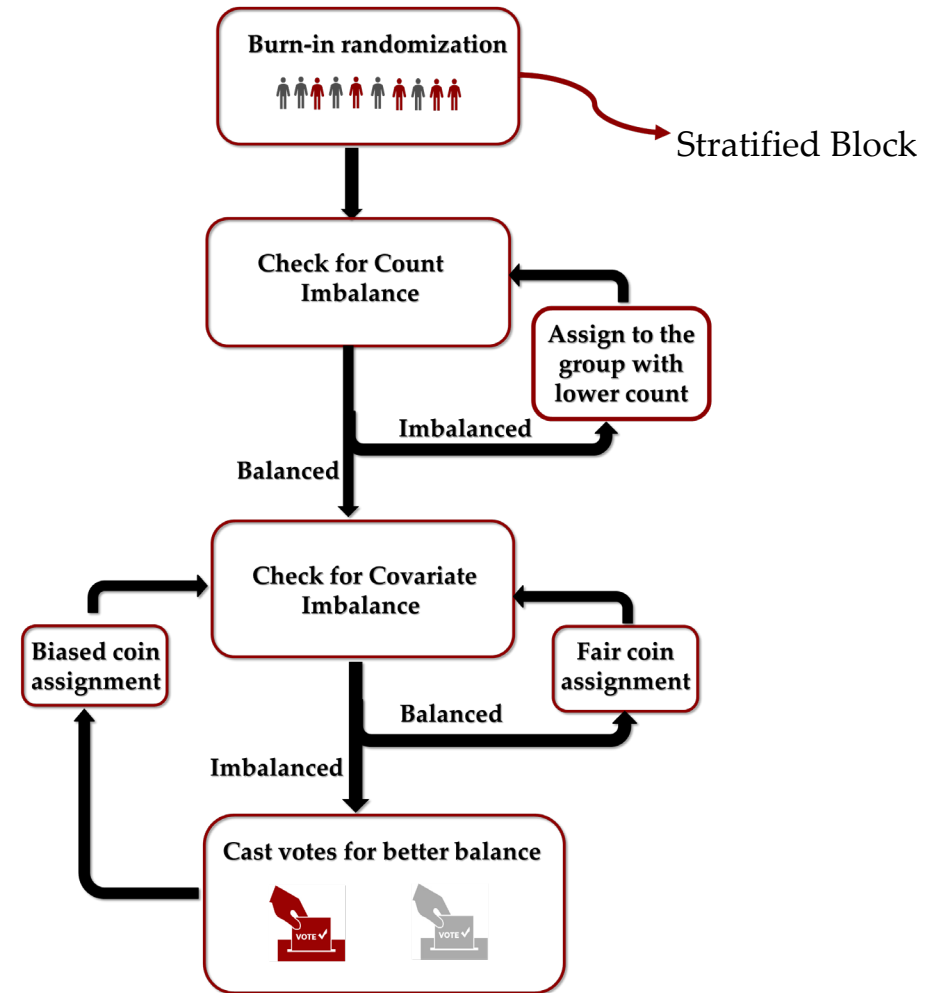

The algorithm tallies these covariate votes to determine preference

Clear Preference

If one arm gets a clear majority, MSB uses a biased coin randomization (e.g., 65/35) favoring that arm

No Strong Preference

If votes are tied or neutral, MSB uses standard 50/50 probability

From Proprietary Software to REDCap

Current instrument: **T1 MSB Randomization (Statisticians, CON)**
Form name: t1_msb_randomization_statisticians_con

The screenshot displays the REDCap form editor interface for the instrument 'T1 MSB Randomization (Statisticians, CON)'. It shows four fields, each with a 'Field Name' and a 'View equation' link. The fields are:

- Field Name: n_msb, labeled '(Total randomized) - (100)'. It is marked as '@HIDDEN'.
- Field Name: es_threshold, labeled 'ES Threshold'. It is marked as '@HIDDEN'.
- Field Name: trt, labeled 'Was participant assigned to intervention?'. It is marked as '@HIDDEN'.
- Field Name: uc, labeled 'Was participant assigned to UC?'. It is marked as '@HIDDEN'.

Each field has a 'View equation' link and is marked as '@HIDDEN'. The interface includes buttons for 'Add Field', 'Add Matrix of Fields', and 'Import from Field Bank' for each field.

Original Implementations

MSB required custom programming or specialized randomization systems when first introduced

Limited Availability

Many trialists stuck with simpler methods due to lack of user-friendly tools for MSB

REDCap's Role

REDCap is widely used for managing clinical trial data but doesn't natively support MSB

Adapting MSB to REDCap

Through REDCap's extensibility, we can integrate MSB into the workflow

Implementing MSB in REDCap – Step by Step

Define Covariates

Decide which baseline covariates to balance and collect before randomization

Indicate Readiness

Set up a field to mark when a participant is ready for randomization

Run MSB Calculations

Hard code effect size calculations for each baseline covariate of interest

Sum Up Votes

Formulas tally votes for all covariates to calculate imbalance and determines allocation using biased coin logic

Return Allocation

REDCap randomization allocation table determines treatment group assignment.

The screenshot displays the REDCap interface for configuring fields under the heading "1. Chronic Conditions". It shows a list of fields with their names and descriptions:

- Field Name: chronic**: Did participant have chronic hypertension, gestational hypertension, preeclampsia, eclampsia, and/or HELLP Syndrome? (View equation)
- Field Name: chronic_uc**: Was current participant assigned to MOMI CARE (UC) and had chronic conditions? (View equation)
- Field Name: chronic_trt**: Was current participant assigned to MOMI PODS (TRT) and had chronic conditions? (View equation)
- Field Name: es_chronic**: Chi-square test statistic for chronic*rand_group for currently assigned participants (View equation)
- Field Name: es_chronic_uc**: Chi-square test statistic for chronic*rand_group if this participant was assigned to UC (View equation)
- Field Name: es_chronic_trt**: Chi-square test statistic for chronic*rand_group if this participant was assigned to TRT (View equation)
- Field Name: flag_chronic**: Flag for chronic conditions (View equation)
- Field Name: vote_chronic**: Vote for chronic conditions (View equation)

Each field entry includes a "View equation" link and a "@HIDDEN" label. At the bottom of each field configuration, there are buttons for "Add Field", "Add Matrix of Fields", and "Import from Field Bank".

MOMI PODS Trial

Burn-in randomization period (first 100 patients randomized) using standard stratified block randomization

Post burn-in randomization period
Study arm allocation imbalance assessed
If the difference in study arm allocation was 4 or more, either *bc0* or *bc6* was utilized, with a deterministic assignment to the arm with fewer patients

(Im)Balance assessed:
If imbalanced, tally votes and utilize the appropriate table. If not imbalanced, default randomization tables were utilized

The screenshot displays the 'Randomization' configuration interface. It features a list of fields with their respective names and configurations:

- total_flags**: Sum of flags, @HIDDEN
- total_votes**: Sum of votes, @HIDDEN
- bi_default_strata**: Burn-in and default strata, @HIDDEN
- bi_default_strata_2**: Burn-in and default strata, with radio button options: Default/Balanced Strata 1, Default/Balanced Strata 2, Default/Balanced Strata 3.
- vote_to_strata**: Vote total to strata - transform, @HIDDEN
- big_stick**: Big stick - calc, @HIDDEN
- combined_strata**: Combined Strata, @HIDDEN
- combined_strata_radio**: Combined Strata, with radio button options: 0 - 0:6 All MOMI CARE, 1 - 1:5 Biased Coin, 2 - 2:4 Biased Coin, 3.1 - 3:3 Strata 1, 3.2 - 3:3 Strata 2, 3.3 - 3:3 Strata 3, 4 - 4:2 Biased Coin, 5 - 5:1 Biased Coin, 6 - 6:0 All MOMI PODS.

Key Takeaways

1. Enhanced Trial Integrity

- MSB provides robust covariate balance with randomization integrity

2. Balances on Key Covariates Without Over Stratification

- Enables for balance on both categorical and continuous baseline covariates, without requiring full stratification, avoiding issues with sparse strata and enabling flexible enrollment

3. Practical Implementation

- Suitable for dynamic trial settings and can be implemented within platforms like REDCap, supporting real-time, site-level allocation decisions

REDCap Randomization Email

Hello,

REDCap Randomization Record ID 1553-5 has been randomized in the PRECISE - TRIPS randomization database.

RedCap Cloud Subject ID: [REDACTED]-1072

Patient has been assigned randomization code: T-2386

Site Pharmacists: please proceed to enter the randomization code in the PRECISE randomization excel table for dosing calculations once study drug has been ordered and confirmed. Please remember this is a double-blind study and no information should be shared with the treating physician or the study team.

Version 4.11.0 (released on 2012-04-27)

- NEW FEATURES & IMPROVEMENTS:

- New Randomization module
- The randomization module in REDCap will help your users implement a defined randomization model within their project, allowing them to randomize their subjects (i.e. records in their project). In this module, they will first define the randomization model with various parameters. Based on the defined parameters, the module creates a template allocation table, which they can use to structure the randomization table that they will import. The module also monitors the overall allocation progress and assignment of randomized subjects.

Available in latest Version 15.4.0 (2025-02)

 Question

alex.cheng (Alex Cheng) asked • 10 months, 3 days ago (2023-10-24 01:55) 

REQUEST: Seeking biostats expertise to inform complex adaptive randomization functionality within REDCap

Background: The most common approach to study design treats the sample size as a fixed target and ignores new data being collected. Although this can simplify power calculations and budgeting, it eliminates scientific flexibility, risks reduced trial power, and misses opportunities for efficiency and safety (e.g., halting trials for strong early evidence of efficacy, inferiority, or harm). Trialists need to be able to use statistical approaches that incorporate flexibility based on the accumulated prior knowledge about the intervention and its effects, as well as the planned use of information gained from the trial as it accrues patients.

Goal: The [Vanderbilt Trial Innovation Center \(TIC\)](#) is seeking to develop complex adaptive randomization capabilities (possibly as external modules) for REDCap to support adaptive randomization within REDCap.

REDCap Randomisation 2.0

Starting November 2023...

Consultation and discussions with a range of stakeholders from VUMC / VICTR and other clinical trials centres:

- Various meetings
- Demonstrations
- Design Studio

Agreed list of enhancements for development

ACCEPTED

1. Multiple randomisations in a project
2. Improve concealed allocation support
3. Smart variables e.g. for time / number
4. Real-time trigger logic
5. Administrator tools for editing
6. API method
7. Hook function

REJECTED

8. Alternative allocation algorithms
9. Medication pack management

REDCap Randomisation 2.0

Intuitive, familiar interface

Summary Setup 1 Dashboard 1

STEP 1: Define your randomization model

This step will allow you to define the randomization model you will be implementing and all its parameters, which includes defining strata (if applicable) and optionally randomizing subjects per group/site (if a multi-site study).

NOTE: This section is currently locked and uneditable because the randomization setup process has already been completed. Because this project is in Production status, the randomization setup values below CANNOT be modified.

A) Use stratified randomization?

It is often necessary to ensure equal treatment among a number of factors. Stratified randomization is the solution to achieve balance within one or more subgroups, such as sex, race, diabetics/non-diabetics, etc. By choosing strata (multiple choice criteria fields), you may then be able to ensure balance within those subgroups. [Tell me more](#)

B) Randomize by group/site?

If this is a multi-center/multi-site project (or something similar), you may want to stratify the randomization by each group/site. You can select an existing multiple choice field that represents the groups/sites, OR you can use Data Access Groups to stratify by group/site.

C) Choose your randomization field

This is the field where the "Randomize" button will appear on your data collection form. The type of field you choose (text field vs. single-select multiple choice field) dictates the Allocation Type for this randomization model.

For open randomization:

- Select a single-select (dropdown or radio) field. The randomized **group allocation** will be saved to this field.

For concealed (blinded) randomization:

- Select a text field that does not have field validation. The assigned **randomization number** will be saved to this field.

Note that the randomization number is available through the smart variable `[rand-number]`.

randomization (Randomization) ▾

Allocation will be **concealed (blinded)** with **randomization number** assigned to this **text** field.

Save randomization model

Erase randomization model

Previous 1 Next

+ Add new randomization model

STEP 2: Download template allocation tables (as Excel/CSV files)

Below are some example files that you may download to get a general idea for how you may structure your own randomization table. You do not have to use any of these. In fact, **we recommend that you NOT use these exact templates** but instead recommend that you merely use them as an example or baseline to start from in order to create your own custom allocation file. After uploading your allocation table in Step 3 below, it will then be used as a lookup table to perform assignments when subjects are being randomized. **NOTE:** Record names (e.g., study ID) should NOT be included as a column in your allocation table, but only the fields listed in the example files below. [More details](#)

Example #1 (basic)

Example #2 (all possible combos)

Example #3 (5x all possible combos)

STEP 3: Upload your allocation table (CSV file)

Once you have created your custom allocation table as a CSV file and made sure that you kept the format prescribed in the template files from Step 2 above, you may now upload the file below. It will be checked for any possible errors first before it is accepted and stored in REDCap. Please note that you will need to create two different allocation tables: one to be used for testing while your project is in development status and the other for use when in production status. Below are some important reminders before you begin uploading your allocation tables.

Reminders:

- Once your project is in production status, the allocation tables will become locked and unmodifiable.
- Be sure to include more assignments in your allocation table than you think you will need (to accommodate possible drop-out and drop-in of subjects).
- Record names (e.g., study ID) should NOT be included as a column in your allocation table, but only the fields listed in the example files from Step 2 above.

2. Improved support for concealed allocation

Randomising user sees only an allocation id - randomisation number

Separate list of number to group mapping:

- In Pharmacy, for medication pack dispensing
- In separate project for code break

- select a field - for Event 1

- select a field -

single-select fields for open allocation

- randstrat1 (Randomization 1 stratum)
- randgrp1 (Randomization 1 group)
- randstrat2 (Randomization 2 stratum)
- randstrat3 (Randomization 3 stratum)
- randgrp3 (Randomization 3 group)

text fields for blinded allocation

- randno1 (Randomization 1 number)
- randtm1 (Randomization 1 time)

randgrp1 (Randomization 1 group) for Event 1

Allocation will be **open** with **randomization group** assigned to this **single-select** choice field.

randno2 (Randomization 2 number: [randomization-number:2] for Event 1

Allocation will be **concealed/blinded** with **randomization number** assigned to this **text** field.

- [rand-number:2]

REDCap Randomisation 2.0

4. Real-time trigger logic

Automatically perform a randomisation on form save when logic condition is true

Inspired by Andy Martin's "Realtime Randomization" external module

Options:

- Off: click "Randomize" button to randomise
- Trigger for users with "Randomize" permission only
- Trigger for all users - including survey

Module title and description	First Submitted	Most Recent Update	Downloads (Installs only - Excludes updates)
Realtime Randomization (<i>realtime_randomization_v1.0.3</i>) View on GitHub View Stats <i>Description:</i> This module allows you to auto-randomize after saving any form without user interaction. It can be used, for example, to randomize someone upon completion of an eligibility survey. It supports logic to control randomization, strata, and Data Access Groups. <i>Authors:</i> Andrew Martin (Stanford University), Ihab Zeedia	2021-04-09	2024-02-16	311

STEP 4: Automatic Triggering Option

Randomization can be automated to occur in real time when an instrument is saved and the logic expression entered here becomes true. All required stratification information must be present.

Trigger option

Instrument

Trigger logic

Tip: you may utilise the smart variables `[is-survey]` or `[is-form]` to provide different behaviour in survey view or on the data entry form.

6. API Method

Randomise a record using an API call from outside REDCap

Facilitate integration of randomisation functionality into other systems and processes

Does not replicate data import method: record must exist and have stratification data

https://localhost/redcapdev2/api/help/index.php?content=randomize

REDCap API Documentation

Method Name
Randomize Record

Description
This method allows the current API user to randomize a record.

URL

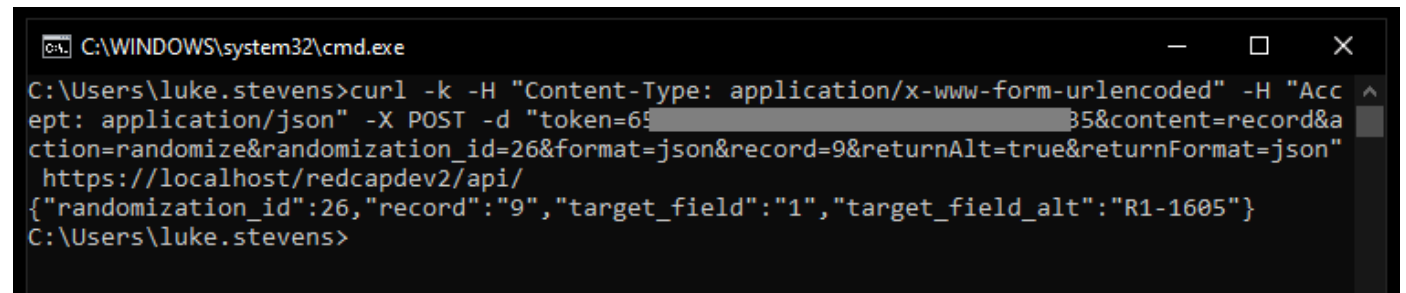

Supported Request Method

Permissions Required
To use this method you must have the Randomize privilege in the project.

Parameters (case sensitive)

Required

- token**
The API token specific to your REDCap project and username (each token is unique to each user for each project). See the section on the left-hand menu for obtaining a token for a given project.
- content**
record
- action**
randomize
- record**
The record name (id) of the record to randomize. The record must already exist and contain all necessary stratification information.
- randomization_id**
The unique id of the randomization (viewable on the Randomization page for users with Design permissions, or on the API Playground page). Corresponds to a specific target field and event.
- format**
csv, json, xml [default], odm ('odm' refers to CDISC ODM XML format, specifically ODM version 1.3.1)

```
C:\WINDOWS\system32\cmd.exe
C:\Users\luke.stevens>curl -k -H "Content-Type: application/x-www-form-urlencoded" -H "Accept: application/json" -X POST -d "token=6!35&content=record&action=randomize&randomization_id=26&format=json&record=9&returnAlt=true&returnFormat=json" https://localhost/redcapdev2/api/
{"randomization_id":26,"record":"9","target_field":"1","target_field_alt":"R1-1605"}
C:\Users\luke.stevens>
```

REDCap Randomisation 2.0

7. Hook Function

Called at the point where REDCap selects the next allocation

Methods for querying the allocation table:

- Read next allocation for stratum
- Update table data

Facilitates development of alternative allocation algorithms e.g. dynamic:

- Update allocation group for record dynamically based on previous allocations

redcap_randomize_record

(REDCap >= 12.7.?)

`redcap_randomize_record` — Allows custom actions to be performed prior to the randomization of a record e.g. to override the default randomization allocation.

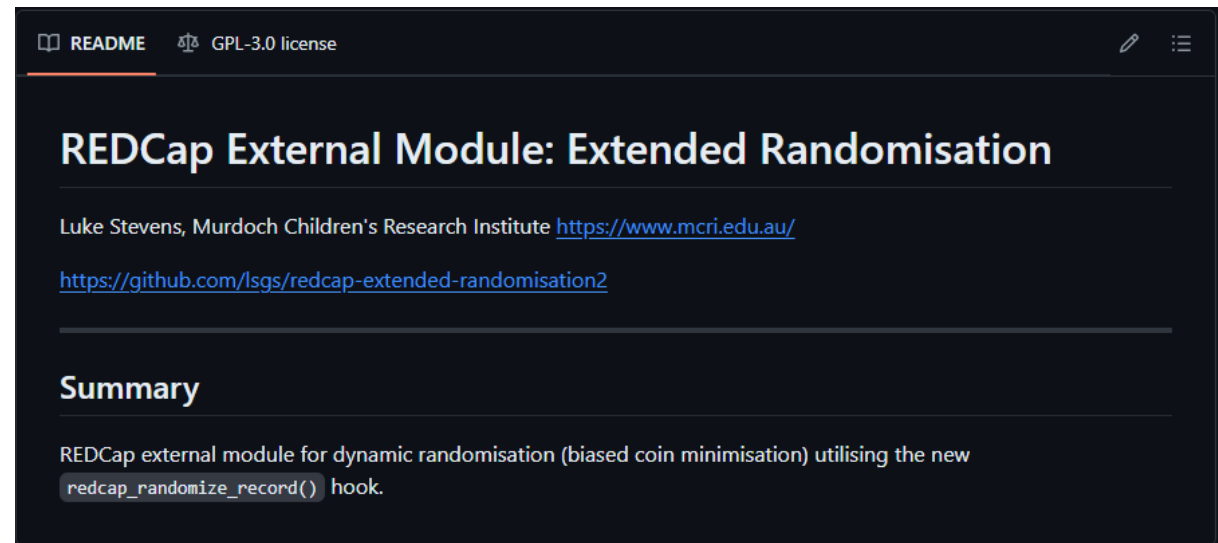

Description

```
void redcap_randomize_record ( int $project_id, int $randomization_id, string $record, array $field_values, int $group_id )
```

It is expected that only one external module implementing this hook will be enabled in a single project. A warning will be generated if multiple external modules return results from this hook.

Location of Execution

The function is executed immediately prior to lookup and assignment of the next available entry in the randomization allocation table. This lookup and allocation is skipped if all `redcap_randomize_record` hooks return false.

The screenshot shows a GitHub README page for the 'REDCap External Module: Extended Randomisation'. At the top, it indicates 'README' and 'GPL-3.0 license'. The title is 'REDCap External Module: Extended Randomisation'. Below the title, the author is listed as 'Luke Stevens, Murdoch Children's Research Institute' with a link to 'https://www.mcri.edu.au/'. A link to the GitHub repository is provided: 'https://github.com/lsgs/redcap-extended-randomisation2'. The 'Summary' section states: 'REDCap external module for dynamic randomisation (biased coin minimisation) utilising the new redcap_randomize_record() hook.'

REDCap Randomisation 2.0

1. Multiple randomisations in a project

Trials are increasing in diversity and complexity*:

- Adaptive trials - randomisation configuration alterations at defined points in trial
- Platform trials - multiple interventions, parallel or sequential

* Zabor, E. C., Kaizer, A. M., & Hobbs, B. P. (2020). Randomized Controlled Trials. *Chest*, 158(1S), S79-S87. <https://doi.org/10.1016/j.chest.2020.03.013>

REDCap Randomisation 2.0

Use case: (intermittent) adaptive randomization

- The PRECISE trial (VanBuren) was response adaptive
- Allocation ratios across 4 dose levels updated at each of 12 interims
- May be accomplished by adding new randomizations at each interim
- Use branching logic to hide old randomizations
- Combine randomizations using calculated field

The screenshot shows the REDCap interface for adding randomization fields. It features three rows, each representing a different randomization field:

- Randomization 1:** Field Name: `randomization_1`, Branching logic: `[randomization_1] <> ""`
- Randomization 2:** Field Name: `randomization_2`, Branching logic: `[randomization_1] = "`
- Randomization:** Field Name: `randomization`, with a [View equation](#) link.

Each row includes buttons for 'Add Field', 'Add Matrix of Fields', and 'Import from Field Bank'.

Calculation equation for variable "randomization"

Variable Name: `randomization`
Field Label: Randomization
Calculation: `if([randomization_1] <> '', [randomization_1], if([randomization_2] <> '', [randomization_2], ''))`

Fields Utilized in Calculation		
Variable Name	Field Label	Form Name
<code>randomization_1</code>	Randomization 1	Randomization
<code>randomization_2</code>	Randomization 2	Randomization

Close

REDCap Randomisation 2.0

Use case: (continuous) adaptive randomization

- Adaptation that occurs prior to each randomization still extra work
- MSB (Palettas) could be implemented using hook function (external module)

redcap_randomize_record

(REDCap >= 1?.?.?)

`redcap_randomize_record` — Allows custom actions to be performed prior to the randomization of a record e.g. to override the default randomization allocation.

Description

```
void redcap_randomize_record ( int $project_id, int $randomization_id, string $record, array $field_values, int $group_id )
```

It is expected that only one external module implementing this hook will be enabled in a single project. A warning will be generated if multiple external modules return results from this hook.

Location of Execution

The function is executed immediately prior to lookup and assignment of the next available entry in the randomization allocation table. This lookup and allocation is skipped if all `redcap_randomize_record` hooks return false.

REDCap Randomisation 2.0

"And remember – with great randomization flexibility comes great responsibility."

Questions?
